Egyptian Academic Journal of Biological Sciences is the official English language journal of the Egyptian Society for Biological Sciences, Department of Entomology, Faculty of Sciences Ain Shams University.

Microbiology journal is one of the series issued twice by the Egyptian Academic Journal of Biological Sciences, and is devoted to publication of original papers related to the research across the whole spectrum of the subject. These including bacteriology, virology, mycology and parasitology. In addition, the journal promotes research on the impact of living organisms on their environment with emphasis on subjects such a resource, depletion, pollution, biodiversity, ecosystem…..etc

**INTRODUCTION**

Nasopharyngeal carcinoma (NPC) is a common Head and Neck Cancer in China, Taiwan and other Asian countries (Waterhouse, et al. 1982). While Epstein–Barr virus (EBV) has been closely linked to NPC (Lun, et al. 2014; Tsang, et al. 2014), hereditary and environmental factors, such as salted fish, Chinese herbs and long-term exposure to sulfuric acid vapor, have also been supposed to be associated with NPC initiation (Armstrong, et al. 1983; Ho, et al. 1999). However, the etiological factors have yet to be clearly identified. In some studies attempted to investigate the molecular mechanism of NPC pathogenesis, they established nine NPC cell lines (Lin, et al. 1990; Lin, et al. 1993). Most of these cell lines indicate that EBV plays a major role in promoting tumor progression in NPC pathogenesis (Wu, et al. 2003; Ryan and Ray, 2004).

**OBJECTIVE**: The aim of this study was to screen for the presence of HSV in patients with nasopharyngeal Carcinoma (NPC).

**METHODOLOGY**: Formalin fixed paraffin wax processed NPC tissue were obtained from 150 tissue blocks and retrospectively investigated for the presence of HSV-1 and HSV-2 using polymerase Chain Reaction (PCR). **RESULTS**: Of the 150 NPC tissue specimens, Herpes Simplex Virus type 2 (HSV-2) was identified in 18/150 (12%) samples. Out of the 18 samples infected with HSV-2, 15/97 (15.5%) among males and 3/53 (5.7%) were among females. **CONCLUSION**: The present have shown some weak links between HSV and NPC. The great majority of samples harboring HSV were also found to harbor EBV, which suggests the potentiality of EBV over HSV.
Herpes simplex virus 1 and 2 (HSV-1 and HSV-2), are two members of the herpesvirus family, that infect humans (Ryan and Ray, 2004). HSV-1 and HSV-2 have developed several mechanisms to escape host detection and immune responses and usually establish lifelong latency (Kenneth, et al. 2014) HSV-1 has been identified in benign and malignant thyroid tumours, whereas HSV-2 has been found to be associated with papillary thyroid cancer and the presence of lymph node metastases (Jensen, et al. 2010) Moreover, HSV-2 is associated with prostate cancer, melanoma incidence in both men and women (Thomas, et al. 2011), and cervical cancer (Haverkos, et al. 2000).

Although the probability of an association between HSV and cancer has been proposed [12,13], but so far it has not been likely to demonstrate that HSV can make primary transformation of normal cells to malignant. Inoculation of HSV-1 and HSV2 into hamsters rarely leads to the induction of a tumor, and it has been difficult to demonstrate herpes viral antigens in a tumor cells (Duff and Rapp, 1971). However, there is a complete lack of literature regarding the relationship between NPC and HSV, therefore, the aim of this study was to screen for the presence of HSV amongst Sudanese patients with PC.

**MATERIALS AND METHODS**

In this study 150 formalin fixed paraffin wax processed tissue samples of nasopharyngeal carcinoma were obtained from earlier operated patients from different histopathology laboratories in Khartoum State, Sudan. All tissue samples were from those who had not yet given anti-cancer therapy. The study was approved by the Ethical Committee of the Research Board of Faculty of Medical Laboratory Science, Sudan University for Science and Technology, Khartoum, Sudan.

DNA Extraction: DNA was extracted from paraffin-embedded samples, by immersing tissue section in xylene to dissolve the paraffin from the tissue, and then rehydrated using a series of ethanol washes. Proteins and harmful enzymes such as nucleases were digested by proteinase K. Buffer containing denaturing agent (sodium dodecyl sulfate (SDS)), was added to facilitate digestion (Hilz, et al. 1975). Nucleic acids were purified from the tissue lysate using buffer-saturated phenol and high speed centrifugation. Following phenol extractions, RNase A was added to eliminate contaminating RNA. Additional phenol extracts following incubation with RNase A were used to remove any remaining enzyme. Sodium acetate and isopropanol were added to precipitate DNA, and high speed centrifugation was used to pellet the DNA and facilitate isopropanol removal. Washing with 70% ethanol was performed to remove excess salts, followed by centrifugation to re-pellet the DNA (Joseph, 2001; Pikor, et al. 2011). DNA is re-suspended in distilled water, quantified and stored at -20°C Purified DNA was subsequently used in downstream applications of PCR.

**RESULTS**

This study investigated retrospectively tissue samples obtained from 150 patients diagnosed with nasopharyngeal carcinoma, their ages ranging from 17 to 88 years with a mean age of 51 years. Male female ratio was 5:00 to 1.00. Of the 150 NPC tissue specimens, Herpes Simplex Virus type 2 (HSV-2) was identified in 18/150 (12%) samples. Out of the 18 samples infected with HSV-2, 15/97 (15.5%) among males and 3/53 (5.7%) were among females. The 95% confidence interval and the odd ratio for sex male/female was 3.049 (840-11.059), P <0.06, as indicated in Fig 1. Moreover, of the 18 HSV positive samples 12/18 (66.7%) were found to harbor EBV.

As indicated in Fig 2, the highest frequency of infection rates were seen among age group (51+) representing 10/77 (13%) followed by age range 21-50 and < 20 years, constituting 7/63 (11%) and 1/10 (10%), in this order.
Is Herpes Simplex Virus (HSV) infection a risk factor for nasopharyngeal carcinoma

In regard to the residence and HSV-2 infection, the great majority of infections were identified among Southern populations, representing 7/22 (24%) followed by Khartoum, Eastern, Northern and Western, constituting 4/27 (14.8%), 3/21(14.3%) and 1/18 (5.4%), respectively, though the West represents the greatest participants, as shown in Table1, Fig 3.

DISCUSSION

In the present study we attempted to investigate the relationship between HSV and NPC, though there is an extreme lack of literature in this context. Herpes simplex virus type 1 (HSV-1) is a widespread human pathogen infecting more than 80% of the population worldwide. Its replication involves an essential, poorly understood multistep process, referred to as uncoating (Liashkovich, et al. 2011).

However, HSV impair the immune system by disturbing T-cell receptor signalling. These viruses inhibit the T-cell receptor (TCR)-stimulated formation of a linker required for the activation of a T-cell signalling complex. As a consequence, TCR-stimulated NF-κB activation and selective TCR-stimulated interleukin-10 synthesis are inhibited, which in turn favoured viral replication and blocked cellular immunity (Sloan, et al. 2007). HSV was found to inhibit the type I interferon response (Murphy, et al. 2003), and HSV-1 infected cells can resist T-cell induced apoptosis through expression of the Us5 gene product gJ (Jerome, et al. 2001). The relationship between HSV immune disturbance and cancer can be expressed by the hypothesis of tumour immunosurveillance. It was stated that the human body employs its natural defences and exhibits immunological resistance to the development of cancer. This immunological response happens during the early stages of cancer growth. The clinically noticeable signs of tumour disease can only be seen after the cancerous cells have already escaped the immune response (Peto, 2001).

Regarding age most of HSV infections were observed among elder patients. Also regarding residence, most infections were seen among those patients coming from South.

In conclusion: The present have shown some weak links between HSV and NPC. The great majority of samples harboring HSV were also found to harbor EBV, which suggests the potentiality of EBV over HSV.

REFERENCES

Hilz H, Wiegers U and Adamietz P. (1975). Stimulation of proteinase K action by reactivations proposes that it may contribute to OSCC development. In fact, *in vitro* studies have clarified specific mechanisms over which HSV1 may induce the transformation of human cells: HSV1 infection of human cell cultures has been revealed to be mutagenic (Das, et al. 1998), and inhibit apoptosis (Jerome, et al. 1998), which may contribute to carcinogenesis (Polverini and Nor, 1999). Some studies found that HSV1 was particularly associated with OSCC risk when other risk factors, such as cigarette smoking or a history of HPV infection, are present (Jacqueline, et al. 2000). Furthermore, the significant presence of co-infection between HSV and EBV, may have synergistic effects in the development of NPC.

In vitro and animal models suggest that the HSV-1 may play a role in the development of oropharyngeal squamous cell carcinoma (OSCC) (Jacqueline, et al. 2000). The persistence of the HSV in the oral cavity and its capability to stimulate host DNA synthesis and repair during reactivations proposes that it may contribute to OSCC development. In fact, *in vitro* studies have clarified specific mechanisms over which HSV1 may induce the transformation of human cells: HSV1 infection of human cell cultures has been revealed to be mutagenic (Das, et al. 1998), and inhibit apoptosis (Jerome, et al. 1998), which may contribute to carcinogenesis (Polverini and Nor, 1999). Some studies found that HSV1 was particularly associated with OSCC risk when other risk factors, such as cigarette smoking or a history of HPV infection, are present (Jacqueline, et al. 2000). ARABIC SUMMARY

هل الإصابة بفيروس الهرابس البسيط (HSV) عامل خطر لسرطان البلعوم؟

حسين جاد الكريم أحمد 1، رانيا سعد عبد القادر سليمان 1، محمد صديق عبد العزيز 2، فواز الشمري 3، فارس ميرغني التوم 4، إبراهيم قيناوي 1.

الهدف: كان الهدف من هذه الدراسة الكشف عن وجود فيروس الهرابس البسيط في المرضى الذين يعانون من سرطان البلعوم (NPC).

الطريقة: تم الحصول على 150 كتلة نسيجية من شمع الباثر البار، ثم التحقق من فيروس الهرابس البسيط 1 و 2 (HSV-1 و HSV-2) باستخدام تفاعل البلمرة التسلسلية (بي سي إم). النتائج: من 150 عينة نسيجية من سرطان البلعوم، تم الكشف عن فيروس الهرابس البسيط من النوع 2 (2-18) في عينة مصابة ب فيروس هربس البسيط 2 (2-18). في الأصل، كانت نسبة الذكور 53/3% والإناث 57/6%.

الخلاصة: التقرير الحالي اظهر بعض الروابط الضعيفة بين فيروس الهرابس البسيط (HSV) وسرطان البلعوم. تم العثور فيروس الهرابس البسيط (HSV) أيضا فيروس ايشتاين بار (EBV) على الغالبية العظمى من العينات مما يشير إلى إمكان حدوث (EBV) خلال HSV.
